Cost Gap d

The parameter d can be interpreted in one of two ways:

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.
2. Information Friction or Statistical Discrimination.

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.
2. Information Friction or Statistical Discrimination.

$$d^t = W(\bar{e}) - \left[W(\tilde{e}) + \frac{W(\hat{e}) - W(\tilde{e})}{\hat{e} - \tilde{e}} (\bar{e} - \tilde{e}) \right].$$

.

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.
2. Information Friction or Statistical Discrimination.

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.
2. Information Friction or Statistical Discrimination.

Let α and β be $r.v.$ drawn from a joint distribution such that $\alpha \leq 0 \leq \beta$.

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.
2. Information Friction or Statistical Discrimination.

Let α and β be $r.v.$ drawn from a joint distribution such that $\alpha \leq 0 \leq \beta$.$\tilde{e} = \bar{e} + \alpha$ and $\hat{e} = \bar{e} + \beta$.

Cost Gap d

The parameter d can be interpreted in one of two ways:

1. Hiring Cost or Taste-Based Discrimination.
2. Information Friction or Statistical Discrimination.

Let α and β be $r.v.$ drawn from a joint distribution such that $\alpha \leq 0 \leq \beta$.$\tilde{e} = \bar{e} + \alpha$ and $\hat{e} = \bar{e} + \beta$.

$$d^s = W(\bar{e}) - \left[E[W(\bar{e} + \alpha)] + \frac{E[W(\bar{e} + \beta)] - E[W(\bar{e} + \alpha)]}{E[\beta - \alpha]} \cdot E[-\alpha] \right].$$

Employer learning implies that $\alpha, \beta \to 0$ over time.

Taste-Based vs. Statistical

The cost gap observed right after graduation is $d = d^t + d^s$.

Taste-Based vs. Statistical

The cost gap observed right after graduation is $d = d^t + d^s$.

As immigrant workers assimilate to the labor market $d^s \to 0$.

Taste-Based vs. Statistical

The cost gap observed right after graduation is $d = d^t + d^s$.

As immigrant workers assimilate to the labor market $d^s \to 0$.

By comparing within-cohort observed d over time, I can bound d^t and d^s.

LinkedIn Profiles

To study whether employer learning reduces education–occupation gaps—something cross-sectional data (e.g., ACS) cannot address—I construct a panel using scraped LinkedIn profiles from People Data Labs.

Current data include:

- Person record (sex, job, location)
- Job experience (date, company, title, role)
- Education (date, school, degree, major)
- Certifications (date, organization)

Matching LinkedIn Job Titles to SOCs

Using 250 distinct job titles for each of the 1,016 SOC codes from LinkUp, I fine-tune a Llama-3.1 (8B) model to classify each self-reported job title into its corresponding SOC code.

Matching LinkedIn Job Titles to SOCs

Using 250 distinct job titles for each of the 1,016 SOC codes from LinkUp, I fine-tune a Llama-3.1 (8B) model to classify each self-reported job title into its corresponding SOC code.

> *Map the job title to its SOC code. Output the code only. For gibberish, use 00-0000.00.*
> *Instruction: Map title to SOC*
> *Input: Vice President, company_name*
> *Response: 11-1011.00*

Matching LinkedIn Job Titles to SOCs

Using 250 distinct posted job titles for each of the O*NET 1,016 SOC codes provided by LinkUp, I fine-tune a Llama-3.1 (8B) model to classify each self-reported job title into its corresponding SOC code.

> *Map the job title to its SOC code. Output the code only. For gibberish, use 00-0000.00.*
> *Instruction: Map title to SOC*
> *Input: Cloud Tree Guitar*
> *Response: 00-0000.00*

LinkedIn Panel

I construct a panel of individuals who attended a U.S. degree-granting post-secondary institution and held at least one job matched to an O*NET SOC code. The sample spans 1970–2025 and includes $\sim$1.4B person-year observations from $\sim$44M individuals, averaging 33 years per person.

Table 2: Combined Education and Employment Statistics

Part 1: By Highest Degree			**Part 2: Education-to-Employment Gap**		
Degree	**Dist. %**	**Jobs**	**Gap Duration**	**Count (N)**	**Pct. %**
Some College	7.53	1.9	Work before (< 0)	28,437,815	64.45
Bachelors	52.50	2.8	Same year (0)	5,314,838	12.05
Masters	31.30	2.6	1 year	2,649,947	6.01
Professional	5.00	2.6	2 years	1,234,768	2.80
PhD	3.70	2.5	3–5 years	2,170,394	4.92
			$>$ 5 years	4,316,303	9.78

Constructing Smooth Education Attainment

Using IPEDS data, I can observe variation in the prestige of schools where each worker acquired their degree.

$$\text{score}_s = 0.65 \times \text{Std. SAT/ACT Scores} + 0.35 \times \text{Std. Rejection Rate}$$

At each degree level, I can then apply the calculated score to proxy for the signaling value of the degree.

$$\mathbb{I}_i = \beta_0 + \sum_{d=\text{Mas.}}^{\text{Pro.}} \delta_d \cdot \mathbb{1}\{Deg_i = d\} + \sum_{d=\text{Bac.}}^{\text{Pro.}} \beta_d \cdot \mathbb{1}\{Deg_i = d\} \cdot (score_i - sc\bar{o}re_d) + \varepsilon$$

Constructing Smooth Education Attainment

General Separating Equilibrium

The general model follows the work of (Mailath, 1987).

Each worker chooses their education according to $\sigma : \Theta \to \mathcal{E}$.
Observing e, the firm updates belief about the worker's type $\widehat{\Theta}(e) \subseteq \Theta$.

In a full **separating** equilibrium, σ is a one-to-one function, i.e.,

$$\widehat{\Theta}(e) = \{\sigma^{-1}(e)\}, \forall e \in \mathcal{E} \tag{1}$$

and $\sigma(\theta)$ must satisfy *strict incentive compatibility*:

$$\{\sigma(\theta)\} = \underset{e}{argmax}\ U(\theta, \sigma^{-1}(e), e), \forall \theta \in \Theta \tag{2}$$

Regularity Conditions

1. (Smoothness) $U(\theta, \hat{\theta}, e)$ is twice differentiable on $\Theta^2 \times \mathcal{E}$.
2. (Belief Monotonicity) $\dfrac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right) > 0$.
3. (Type monotonicity) $\dfrac{\partial^2}{\partial \theta \partial e} U\left(\theta, \hat{\theta}, e\right) > 0$
4. ("Strict" Quasi-Concavity) $\frac{\partial}{\partial e} U\left(\theta, \hat{\theta}, e\right) = 0$ has a unique solution in e, denoted $\phi(\theta)$ such that $\phi(\theta) \in \underset{e}{argmax}\ U\left(\theta, \hat{\theta}, e\right)$, and $\dfrac{\partial^2}{\partial e^2} U\left(\theta, \hat{\theta}, e\right)\bigg|_{e=\phi(\theta)} < 0$.
5. (Boundedness) $\exists k > 0$ such that

$$\forall (\theta, e) \in \Theta \times \mathcal{E}, \frac{\partial^2}{\partial e^2} U(\theta, \hat{\theta}, e) \geq 0 \ \Rightarrow \ \left| \frac{\partial}{\partial e} U(\theta, \hat{\theta}, e) \right| > k.$$

Additionally, there are two niceness conditions: Initial Value (IV) and Single Crossing (SC).

Characterization of the Solution

Mailath (1987) shows that
If conditions 1-5 are satisfied, then a strictly increasing function σ, continuous at $\underline{\theta}$, satisfies strict incentive compatibility if and only if:

1. σ solves $\dfrac{d\sigma}{d\theta} = -\dfrac{\frac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right)}{\frac{\partial}{\partial e} U\left(\theta, \hat{\theta}, e\right)}$

2. when $\frac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right) > 0$, $\dfrac{\frac{\partial}{\partial e} U\left(\theta, \hat{\theta}, e\right)}{\frac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right)}$ is a strictly increasing function of θ.

Moreover, the strictly increasing σ that satisfies strict incentive compatibility is unique.

Characterization of the Solution

Mailath (1987) shows that
If conditions 1-5 are satisfied, then a strictly increasing function σ, continuous at $\underline{\theta}$, satisfies strict incentive compatibility if and only if:

1. σ solves $\dfrac{d\sigma}{d\theta} = -\dfrac{\frac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right)}{\frac{\partial}{\partial e} U\left(\theta, \hat{\theta}, e\right)}$
2. when $\frac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right) > 0$, $\dfrac{\frac{\partial}{\partial e} U\left(\theta, \hat{\theta}, e\right)}{\frac{\partial}{\partial \hat{\theta}} U\left(\theta, \hat{\theta}, e\right)}$ is a strictly increasing function of θ.

Moreover, the strictly increasing σ that satisfies strict incentive compatibility is unique.

In other words, there is an unique full separating equilibrium in the natives' labor market given the assumptions in the basic model environment.
